

METHODOLOGICAL NOTES

Final energy consumption by sectors

The final energy consumption by sectors is an indicator from the Overall Energy Balance of the country, measured in thousand tonnes of oil equivalent.

The indicator measures the energy end-use in a country excluding all non-energy use of energy carriers (e.g. natural gas used not for combustion but for producing chemicals). Final energy consumption only covers the energy consumed by end users, such as industry, transport, households, services and agriculture, and forestry. It excludes fuels for transformation, energy consumption of the energy sector itself and losses occurring during transformation, transmission and distribution of energy, marine bunkering and international aviation.
